Abstract

Matrix-assisted laser desorption ionization-time of flight (MALDI-TOF) mass spectrometry has emerged as a reliable technique to identify molds involved in human diseases, including dermatophytes, provided that exhaustive reference databases are available. This study assessed an online identification application based on original algorithms and an extensive in-house reference database comprising 11,851 spectra (938 fungal species and 246 fungal genera). Validation criteria were established using an initial panel of 422 molds, including dermatophytes, previously identified via DNA sequencing (126 species). The application was further assessed using a separate panel of 501 cultured clinical isolates (88 mold taxa including dermatophytes) derived from five hospital laboratories. A total of 438 (87.35%) isolates were correctly identified at the species level, while 26 (5.22%) were assigned to the correct genus but the wrong species and 37 (7.43%) were not identified, since the defined threshold of 20 was not reached. The use of the Bruker Daltonics database included in the MALDI Biotyper software resulted in a much higher rate of unidentified isolates (39.76 and 74.30% using the score thresholds 1.7 and 2.0, respectively). Moreover, the identification delay of the online application remained compatible with real-time online queries (0.15 s per spectrum), and the application was faster than identifications using the MALDI Biotyper software. This is the first study to assess an online identification system based on MALDI-TOF spectrum analysis. We have successfully applied this approach to identify molds, including dermatophytes, for which diversity is insufficiently represented in commercial databases. This free-access application is available to medical mycologists to improve fungal identification.

Keywords: MALDI-TOF mass spectrometry; dermatophytes; filamentous fungi; fungi; mass spectrometry; online identification.

TABLE 3

Panel 2 identification results obtained with the five identification systems

Result for panel 2 sequenced strains ^a	No. (%) of strains identified				
	IHEM/MRS-MSI (threshold = 20)	IHEM/MRS-MBT (threshold = 1.7)	IHEM/MRS-MBT (threshold = 2.0)	Bruker-MBT (threshold = 1.7)	Bruker-MBT (threshold = 2.0)
Correct at the species level	435 (87.35)	411 (82.53)	312 (62.65)	259 (52.01)	119 (23.9)
Correct at the genus level	26 (5.22)	34 (6.83)	12 (2.41)	41 (8.23)	9 (1.81)
False at the genus level	0 (0)	0 (0)	0 (0)	0 (0)	0 (0)
Identification criteria not met	37 (7.43)	53 (10.64)	174 (34.94)	198 (39.76)	370 (74.3)

[Open in a separate window](#)

^aFor each database/software combination, the number (%) of strains is specified. Correct, concordant with the molecular identification at either the species or the genus level. False, discordant with the molecular identification at the genus level. Identification criteria not met, score below the defined threshold.

TABEAU 3.1 – Impact de la machine et de l’alignement avec MSIWarp. Performance de l’identification des isolats appartenant à l’ensemble des clones par le modèle CNN (validation croisée sur 5 plis). Moyenne des ensembles d’entraînement de 1355 spectres obtenus sur trois machines et moyenne des ensembles de test de 113 spectres obtenus sur la quatrième machine.

Spectres en mode ions négatifs

Conclusion

La spectrométrie de masse : l'avenir de la mycologie ?

- Pour beaucoup c'est déjà le présent
- Offre de belles perspectives d'avenir
 - Capacité à affiner le diagnostic d'espèce
 - Possibilité de travailler en ligne
 - Développement IA possibles
 - Mise en commun des savoirs
